

1.1 - 1.2 Week 1 set up (Understanding & Installing company software / Answers to questions / learning material)

- What does a package manager like Homebrew actually do, and why do we use it instead of downloading installers?
 - Homebrew installs the command-line tools and applications you need.
 - Utilise home-brew over installers because it offerers a centralised way of installing software via CLI. also has many advantages of installing over internet e.g. easier uninstalling process and a better possibility to update the installed software packages.
- These four commands all return something sensible, and you've pasted the output into the worksheet.
 - `{{node -v}}` and `{{npm -v}}` - both these commands are to see which verision is installed onto the device. Node -v see what version of node is installed / npm -v (npm stands for node packet manger) see which version of nodes packet manger is installed on the device.
 - `{{terraform --version}}` - seeing what version of terraform had been installed onto the device / also used to see gif terraform had been installed on the device.
 - `{{aws --version}}` - see what version of AWS is installed on the device.
 - NOTE: when a v command is sent it will send back a result like V1.2.3 that is the version of the software you have asked for.
